

The Moon

The Moon is the Earth's only natural satellite. A natural satellite is a celestial body that orbits around another celestial body. The Moon completes an orbit of the Earth every 27.3 days. It is the fifth largest Moon in the solar system and is located almost 240,000 miles from Earth.

Scientists believe that the Moon is composed primarily of iron, but it may also contain sulfur and other elements. Its core is believed to be only about one to two percent of its mass and about 420 miles wide. Its mantle (the layer between the core and the crust) is about 825 miles thick. It is composed of iron and magnesium-rich rocks.

The Moon formed between 30 and 50 million years after the formation of the Earth. Scientists believe that after a large object struck the Earth, scattering rocks out into the solar system, that some of these rocks came close to each other as they orbited the Earth, eventually melted together, and then cooled down to become what is now Earth's moon. Other rocks continued to strike the moon's surface for hundreds of millions of years, causing the small craters, pits, and scars that you can now see with binoculars or a small telescope.

In the early 17th century, the scientist Galileo made the first map of the moon. He used a telescope he had designed himself that could magnify things up to 20 times.

In the 1950s, as the U.S. fell behind the Soviets in the Space Race, a U.S. Air Force project called Project A119 considered detonating a nuclear bomb on the Moon as the government looked for some way to reassure Americans that the U.S. still had the scientific upper hand. The famous astronomer and author Carl Sagan worked as one of the mathematicians on the project. Fortunately, after much scientific planning and debate, the program was ultimately cancelled.
